SUMMARY

We describe the remapped particle-mesh advection method, a new mass-conserving method for solving the density equation which is suitable for combining with semi-Lagrangian methods for compressible flow applied to numerical weather prediction. In addition to the conservation property, the remapped particle-mesh method is computationally efficient and at least as accurate as current semi-Lagrangian methods based on cubic interpolation. We provide results of tests of the method in the plane, results from incorporating the advection method into a semi-Lagrangian method for the rotating shallow-water equations in planar geometry, and results from extending the method to the surface of a sphere.

KEYWORDS: Semi-Lagrangian advection Mass conservation Particle-mesh method Spline interpolation

1. INTRODUCTION

The semi-implicit semi-Lagrangian (SISL) method, as originally introduced by Robert (1982), has become very popular in numerical weather prediction (NWP). The semi-Lagrangian aspect of SISL schemes allows for a relatively accurate treatment of advection while at the same time avoiding step size restrictions of explicit Eulerian methods. The standard semi-Lagrangian algorithm (see, e.g., Staniforth and Coté (1991)) calculates departure points, i.e., the positions of Lagrangian particles which will be advected onto the grid during the time step. The momentum and density equations are then solved along the trajectory of the particles. This calculation requires interpolation to obtain velocity and density values at the departure point. It has been found that cubic Lagrangian and cubic spline interpolation are both accurate and computationally tractable (see, e.g., Staniforth and Coté (1991)).

Ideally, as well as being efficient and accurate, a density advection scheme should exactly preserve mass in order to be useful for, e.g., climate prediction or atmospheric chemistry calculations. Recent developments have involved computing the change in volume elements, defined between departure and arrival points, making use of a technique called cascade interpolation (Purser and Leslie, 1991). Several such methods have been suggested in recent years, including the methods of Nair and Machenhauer (2002); Nair et al. (2002); Nair et al. (2003) and the SLICE schemes of Zerroukat et al. (2002); Zerroukat et al. (2004); Zerroukat et al. (2006a); Zerroukat et al. (2006b).

In this paper, we give a new density advection scheme, the remapped particle-mesh method, which is based on the particle-mesh discretisation for the density equation used in the Hamiltonian Particle-Mesh (HPM) method suggested by Frank et al. (2002), which itself is a combination of smoothed particle-hydrodynamics (Lucy, 1977; Gingold and Monaghan, 1977) and particle-in-cell methods (Harlow, 1964). The particle-mesh method provides a very simple discretisation which conserves mass by construction, and may be adapted to
nonplanar geometries such as the sphere (Frank and Reich, 2004). In this paper, we show that an efficient scheme can be obtained by mapping the particles back to the grid after each time step. Our numerical results show that this scheme is of comparable accuracy to other mass-conserving semi-Lagrangian advection schemes. We show how the method may be included in the staggered semi-Lagrangian schemes, proposed by Staniforth *et al.* (2006) and Reich (2006), and show how to adapt it to spherical geometry.

In section 2, we describe the particle-mesh discretisation for the density equation. The method is modified to form the remapped particle-mesh method in section 3. We discuss issues of efficient implementation in section 4 and an extension to spherical geometry in section 5. In section 6, we give numerical results for rotating shallow-water simulations using the remapped particle-mesh method in the staggered leapfrog scheme (Reich, 2006). We give a summary of our results and discussion in section 7.

2. Continuity equation and particle advection

In this section we describe the particle-mesh discretisation for the density equation. This discretisation forms the basis for the remapped particle-mesh method discussed in this paper. For simplicity, we restrict the discussion to two-dimensional flows.

We begin with the continuity equation

$$\rho_t + \nabla \cdot (\rho \mathbf{u}) = 0,$$

where $\rho$ is the density and $\mathbf{u} = (u, v)^T \in \mathbb{R}^2$ is the fluid velocity. We write (1) in the Lagrangian formulation as

$$\frac{D \mathbf{X}}{Dt} = \mathbf{u},$$

$$\rho(x, t) = \int \rho^0(x^0) \delta(x - \mathbf{X}(x^0, t)) \, dA(x^0),$$

where $\delta(\cdot)$ denotes the Dirac delta function, and $\rho^0(x)$ denotes the infinitesimal area element at $x^0 = (x^0, y^0)^T \in \mathbb{R}^2$, $\rho(x, t)$ is the density at time $t \geq 0$ at a fixed Eulerian position $x = (x, y)^T \in \mathbb{R}^2$,

$$\frac{D}{Dt}(\cdot) = (\cdot)_t + (\cdot)_x u + (\cdot)_y v$$

is the Lagrangian time derivative,

$$\mathbf{X}(x^0, t) = (X(x^0, t), Y(x^0, t))^T \in \mathbb{R}^2$$

is a Lagrangian particle position at time $t$ with initial position $\mathbf{X}(x^0, 0) = x^0 \in \mathbb{R}^2$, and $\rho^0(x) = \rho(x, 0)$ is the initial density.

To discretise the integral representation (3), we introduce a finite set of Lagrangian particles $\mathbf{X}_\beta(t) = (X_{\beta}(t), Y_{\beta}(t))^T \in \mathbb{R}^2$, $\beta = 1, \ldots, N$, and a fixed Eulerian grid $\mathbf{x}_{k,l} = (x_k, y_l)^T = (k \cdot \Delta x, l \cdot \Delta y)^T$, $k, l = 0, \ldots, M$. Then we approximate the Eulerian grid density $\rho_{k,l}(t) \approx \rho(\mathbf{x}_{k,l}, t)$ by

$$\rho_{k,l}(t) := \sum_\beta \rho^0(\mathbf{x}_\beta^0) \psi_{k,l}(\mathbf{X}_\beta(t)) A_\beta,$$
where $\psi_{k,l}(x) \geq 0$ are basis functions, which satisfy $\int \psi_{k,l}(x) \, dA(x) = 1$. The particles are initially arranged on a uniform grid with grid cell areas denoted by $A_\beta$. Equation (6) may be simplified to
\begin{equation}
\rho_{k,l}(t) = \sum_\beta m_\beta^0 \psi_{k,l}(X_\beta(t)),
\end{equation}
where $m_\beta^0 := \rho_\beta^0 A_\beta$ is the “mass” of particle $\beta$ and $\rho_\beta^0 := \rho_\beta^0(x_\beta^0)$.

Let us now also request that the basis functions $\psi_{k,l}$ satisfy the partition-of-unity (PoU) property
\begin{equation}
\sum_{k,l} \psi_{k,l}(x) A_{k,l} = 1, \quad A_{k,l} := \Delta x \Delta y,
\end{equation}
for all $x \in \mathbb{R}^2$. This ensures that the total mass is conserved since
\begin{equation}
\sum_{k,l} \rho_{k,l}(t) A_{k,l} = \sum_{k,l} \sum_\beta m_\beta^0 \psi_{k,l}(X_\beta(t)) A_{k,l} = \sum_\beta m_\beta^0,
\end{equation}
which is constant. The time evolution of the particle positions $X_\beta(t)$ is simply given by
\begin{equation}
\frac{d}{dt} X_\beta = u_\beta.
\end{equation}

Given a time-dependent (Eulerian) velocity field $u(x, t)$, we can discretise (7) and (10) in time with a simple differencing method:
\begin{equation}
X_{\beta}^{n+1} = X_{\beta}^n + \Delta t u_{\beta}^{n+1/2}, \quad u_{\beta}^{n+1/2} := u(X_{\beta}^n, t_{n+1/2}),
\end{equation}
\begin{equation}
\rho_{k,l}^{n+1} = \sum_\beta m_\beta^0 \psi_{k,l}(X_{\beta}^{n+1}).
\end{equation}

In Frank et al. (2002), this discretisation was combined with a time stepping method for the momentum equation to form a Hamiltonian particle-mesh method for the rotating shallow-water equations. The masses $m_\beta^0$ were kept constant throughout the simulation. We note that the HPM advection scheme is somewhat similar to the Lagrangian advection scheme, as proposed by Kaas et al. (1997), using tracer points.

In this paper, we instead combine the HPM discretisation with a remapping technique so that the particles trajectories start from grid points at the beginning of each time step. Similar to other mass-conserving advection schemes, our remapping approach requires the assignment of new particle “masses” in each time step. Contrary to the volume-based (finite-volume type) remapping strategy of, for example, Nair and Machenhauer (2002), we assign mass-parcels to each grid point, which are moved downstream to provide the density approximation as a superposition of these parcels. This approximation can be implemented very efficiently. The resulting remapping conserves mass globally but not locally (in contrast to volume-based remapping methods). A related downstream advection scheme has been proposed by Laprise and Plante (1995). However, the definition of mass-parcels and the assignment of mass is fundamentally different.
3. Remapped particle-mesh method

In this section, we describe the remapped particle-mesh method for solving the continuity equation. The aim is to exploit the mass conservation property of the particle-mesh method whilst keeping an Eulerian grid data structure for velocity updates. To achieve this we reset the particles to an Eulerian grid point at the beginning of each time step, i.e.,

\[ X^n_\beta = x^n_\beta := x_{k,l}, \quad \beta = 1 + k + l \cdot (M + 1). \] (13)

This step requires the calculation of new particle "masses" \( m^n_\beta, \beta = 1, \ldots, N \), according to

\[ \rho^n_{k,l} = \sum_\beta m^n_\beta \psi_{k,l}(x^n_\beta) \] (14)

for given densities \( \rho^n_{k,l} \). This is the remapping step. We finally step the particles forward and calculate the new density on the Eulerian grid using equations (11)-(12) with \( m^0_\beta \) being replaced by \( m^n_\beta \). Note that the Lagrangian trajectory calculation (11) can be replaced by any other consistent forward trajectory approximation. Exact trajectories for a given time-independent velocity field \( \mathbf{u}(\mathbf{x}) \) will, for example, be used in the numerical experiments.

The whole process is mass conserving since the PoU property (8) ensures that

\[ \sum_\beta m^n_\beta = \sum_{k,l} \sum_\beta m^n_\beta \psi_{k,l}(X^{n+1}_\beta) A_{k,l} = \sum_{k,l} \rho^{n+1}_{k,l} A_{k,l} = \sum_\beta m^{n+1}_\beta. \] (15)

4. Efficient implementation

This density advection scheme can be made efficient since all the interpolation takes place on the grid; this means that the same linear system of equations, characterized by (14), is solved at each time step. The particle trajectories are uncoupled and thus may even be calculated in parallel.

The computation of the particle masses in (14) leads to the solution of a sparse matrix system. We discuss this issue in detail for (area-weighted) tensor product cubic B-spline basis functions, defined by

\[ \psi_{k,l}(\mathbf{x}) := \frac{1}{\Delta x \Delta y} \psi_{cs} \left( \frac{x - x_k}{\Delta x} \right) \cdot \psi_{cs} \left( \frac{y - y_l}{\Delta y} \right), \] (16)

where \( \psi_{cs}(r) \) is the cubic B-spline

\[ \psi_{cs}(r) = \begin{cases} \frac{2}{3} - |r|^2 + \frac{1}{2}|r|^3, & |r| \leq 1, \\ \frac{1}{6}(2 - |r|)^3, & 1 < |r| \leq 2, \\ 0, & |r| > 2. \end{cases} \] (17)

The basis functions satisfy

\[ \sum_{k,l} \psi_{k,l}(\mathbf{x}) A_{k,l} = 1 \] (18)

and

\[ \int \psi_{k,l}(\mathbf{x}) \, dA(\mathbf{x}) = 1 \] (19)
as required.

A few basic manipulations reveal that (14) becomes equivalent to

\[ \rho_{k,l}^n A_{kl} = \rho_{k,l}^n \Delta x \Delta y = \left( 1 + \frac{\Delta x^2}{6} \delta_x^2 \right) \left( 1 + \frac{\Delta y^2}{6} \delta_y^2 \right) m_{k,l}^n \]  

Eq. (20) implies that the particle masses can be found by solving a tridiagonal system along each grid line (in each direction). It is instructive to compute the response function for (20), i.e., to evaluate the resulting masses \( m_{k,l}^n \) for a density \( \rho_{k,l}^n \) that is concentrated at a single grid point. The response function for \( \Delta x = \Delta y = 1 \) can be found in Fig. 1. It can be seen that the resulting values for \( m_{k,l}^n \) are non-zero in an extended neighborhood and some values are even negative. The implication is that the cubic B-spline approach does not satisfy strict local mass-conservation, can potentially lead to negative masses, and does not preserve monotonicity. Negative masses can be avoided by a local redistribution of mass values (such that total mass is conserved). At present it is not clear how to preserve strict monotonicity under cubic B-spline interpolation in a systematic manner.

If the cubic spline \( \psi_{cs} \) in (16) is replaced by the linear spline

\[ \psi_{ls}(r) = \begin{cases} 1 - |r|, & |r| \leq 1, \\ 0, & |r| > 1, \end{cases} \]  

Figure 1. Resulting mass values \( m_{k,l} \) for a density \( \rho_{k,l} \) concentrated at a single grid point. The mesh-size is \( \Delta x = \Delta y = 1 \).
then the system (14) is solved by
\[ m_{k,l}^n = \Delta x \Delta y \rho_{k,l}^n. \] (23)
The resulting low-order advection scheme possesses the desirable property that \( \rho_{k,l}^n \geq 0 \) for all \( k, l \) implies that \( \rho_{k,l}^{n+1} \geq 0 \) for all \( k, l \). Local conservation of mass, in the sense of finite-volume methods, and monotonicity are now also achieved. In general, a remapping with linear splines can lead to undesirable levels of numerical diffusion. However, implementations for the rotating shallow-water equations in planar geometry give encouraging results. See the numerical results in section 6.

It should also be noted that it is not necessary to remap the particles to a grid position after each single time step as long as the particles keep a relative uniform distribution.

On a more abstract level, conservative advection schemes can be derived for general (e.g. triangular) meshes with basis functions \( \phi_{kl}(x) \geq 0 \), which form a partition of unity. An appropriate quadrature formula for (3) leads then to a discrete approximation of type (7). This extension will be the subject of a forthcoming publication.

5. Extension to the sphere

In this section we suggest a possible implementation of the remapped particle-mesh method for the density equation on the sphere. The method follows the particle-mesh discretisation given by Frank and Reich (2004), combined with a remapping to the grid.

We introduce a longitude-latitude grid with equal grid spacing \( \Delta \lambda = \Delta \theta = \pi/J \). The latitude grid points are offset a half-grid length from the poles. Hence we obtain grid points \((\lambda_k, \theta_l)\), where \( \lambda_k = k \Delta \lambda, \theta_l = -\frac{\pi}{2} + (l - 1/2) \Delta \theta \), \( k = 1, \ldots, 2J \), \( l = 1, \ldots, J \), and the grid dimension is \( 2J \times J \).

Let \( \psi_{k,l}(x) \) denote the (area-weighted) tensor product cubic B-spline centered at a grid point \( x_{kl} \in \mathbb{R}^3 \) with longitude-latitude coordinates \((\lambda_k, \theta_l)\), i.e.
\[ \psi_{k,l}(x) := \frac{1}{A_{k,l}} \psi_{cs} \left( \frac{\lambda - \lambda_k}{\Delta \lambda} \right) \cdot \psi_{cs} \left( \frac{\theta - \theta_l}{\Delta \theta} \right), \] (24)
where \((\lambda, \theta)\) are the spherical coordinates of a point \( x = (x, y, z)^T \in \mathbb{R}^3 \) on the sphere, \( \psi_{cs}(r) \) is the cubic B-spline as before, and
\[ A_{k,l} := R^2 \cos(\theta_l) \Delta \theta \Delta \lambda. \] (25)
We convert between Cartesian and spherical coordinates using the formulas
\[ x = R \cos \lambda \cos \theta, \quad y = R \sin \lambda \cos \theta, \quad z = R \sin \theta, \] (26)
and
\[ \lambda = \tan^{-1} \left( \frac{y}{x} \right), \quad \theta = \sin^{-1} \left( \frac{z}{R} \right). \] (27)

At each time step we write the fluid velocity in 3D Cartesian coordinates and step the particles \( X_{i,j} \) forward. We then project the particle positions onto the surface of the sphere as described by Frank and Reich (2004). The Lagrangian trajectory algorithm is then:
\[ X_{i,j}^{n+1} = x_{i,j} + \Delta t u_{i,j}^{n+1/2} + \mu x_{i,j}, \] (28)
where $\mu$ is a Lagrange multiplier chosen so that $\|X_{i,j}^{n+1}\| = R$ on a sphere of radius $R$. This algorithm can be replaced by any other consistent forward trajectory approximation. Exact trajectories are, for example, used in the numerical experiments.

We compute the particle masses $m_{i,j}^n$ by solving the system
\begin{equation}
\rho_{k,l}^n = \sum_{i,j} m_{i,j}^n \psi_{k,l}(x_{i,j}) \tag{29}
\end{equation}
for given densities $\rho_{k,l}^n$. The density at time-level $t_{n+1}$ is then determined by
\begin{equation}
\rho_{k,l}^{n+1} = \sum_{i,j} m_{i,j}^n \psi_{k,l}(X_{i,j}^{n+1}). \tag{30}
\end{equation}

Note that the system (29) is equivalent to
\begin{equation}
\rho_{k,l}^n \Delta A_{k,l} = \left(1 + \frac{\Delta t^2}{6} \frac{\delta_x^2}{\Delta x^2} \right) \left(1 + \frac{\Delta t^2}{6} \frac{\delta_\theta^2}{\Delta \theta^2} \right) m_{k,l}^n \tag{31}
\end{equation}
and can be solved efficiently as outlined in section 4. The implementation of the remapping method is greatly simplified by making use of the periodicity of the spherical coordinate system in the following sense. The periodicity is trivial in the longitudinal direction. For the latitude, a great circle meridian is formed by connecting the latitude data separated by an angular distance $\pi$ in longitude (or $J$ grid points). See, for example, the paper by Spotz et al. (1998). It is then efficient to solve the system (31) using a direct solver.

Conservation of mass is encoded in
\begin{equation}
\sum_{k,l} \rho_{k,l}^{n+1} A_{k,l} = \sum_{k,l} \rho_{k,l}^n A_{k,l}, \tag{32}
\end{equation}
which holds because of the PoU property
\begin{equation}
\sum_{k,l} \psi_{k,l}(x) A_{k,l} = 1. \tag{33}
\end{equation}

6. Numerical results

(a) 1D convergence test

Following Zerroukat et al. (2006a), we test the convergence rate of our method for one-dimensional uniform advection of a sine wave over a periodic domain $\Omega = [0, 1)$. The initial distribution is
\begin{equation}
\rho_0(x) = \sin(2\pi x) \tag{34}
\end{equation}
and the velocity field is $u(x, t) = U = 1$. The 1D version of our method is used to solve the continuity equation
\begin{equation}
\rho_t = -(\rho u)_x. \tag{35}
\end{equation}
The experimental setting is equivalent to that of Zerroukat et al. (2006a). Table 1 displays the convergence of $l_2$ errors as a function of resolution $\Delta x = 1/M$. Note that the results from Table 1 are in exact agreement with those displayed in Table I of Zerroukat et al. (2006a) for the parabolic spline method (PSM) and fourth-order accuracy is observed. The observed equivalence between our remapped particle-mesh advection scheme and PSM only holds for one-dimensional uniform advection. In particular, the extension to multi-dimensions (Zerroukat et al., 2006b) is fundamentally different.
TABLE 1. Convergence of $l_2$-errors as a function of $\Delta x = 1/M$ for uniform advection with $U = 1$ of a sine wave on a periodic domain $\Omega = [0, 1)$ with $\Delta t = 0.12\Delta x/U$ and 20 time steps.

(b) 2D planar advection: Slotted-cylinder problem

The slotted-cylinder problem consists of a solid-body rotation of a slotted cylinder in a flow field that rotates with constant angular velocity about a fixed point. We implemented the slotted-cylinder problem as, for example, described in Nair et al. (1999a); Zerroukat et al. (2002).

Results for the newly proposed advection scheme can be found in Fig. 2. We also computed the root-mean-square (rms) difference between the pointwise (rms$_1$) and the grid-box-averaged (rms$_2$) analytic solution and the numerical one as well as the relative error in total mass (pdm). See Zerroukat et al. (2002) for a
The remapped particle-mesh advection scheme

![Figure 3. Cyclogenesis problem. Top panel: numerical solution at time $t = 5$. Bottom panel: error (analytic minus numerical) with contour minimum $-0.627$ and contour interval $0.418$; error measures, as defined in Zerroukat et al. (2002), $\text{rms}_1 = 0.081439$, $\text{rms}_2 = 0.037703$, and $\text{pdm} = -0.176259\%$.](image)

precise definition of these error measures. It is found that the rms values for our method are slightly smaller than those reported in Zerroukat et al. (2002).

(c) 2D planar advection: Idealized cyclogenesis problem

The idealized cyclogenesis problem (see, e.g., Nair et al. (1999a); Zerroukat et al. (2002)) consists of a circular vortex with a tangential velocity $V(r) = v_0 \tanh(r)/\text{sech}^2(r)$, where $r$ is the radial distance from the centre of the vortex $(x_c, y_c)$ and $v_0$ is a constant chosen such that the maximum value of $V(r)$ is unity. The analytic solution $\rho(x, t)$ is

$$
\rho(x, t) = -\tanh \left( \frac{y - y_c}{\delta} \right) \cos(\omega t) - \left( \frac{x - x_c}{\delta} \right) \sin(\omega t) \right), \quad (36)
$$

where $\omega = V(r)/r$ is the angular velocity and $\delta = 0.05$. The experimental setting is that of Nair et al. (1999a); Zerroukat et al. (2002). In particular, the domain of integration is $\Omega = [0, 10] \times [0, 10]$ with a $129 \times 129$ grid. The time step is $\Delta t = 0.3125$ and a total of 16 time steps is performed. Numerical reference solutions can be found in Zerroukat et al. (2002) for the standard bicubic
and several conservative SL methods. The corresponding results for the newly proposed advection scheme can be found in Fig. 3. It turns out that the rms values of the newly proposed advection scheme are about the same size as those reported by Zerroukat et al. (2002).}

(d) Spherical advection: Solid body rotation

Solid body rotation is a commonly used experiment to test an advection scheme over the sphere. We apply the experimental setting of Nair and Machenhauer (2002); Nair et al. (2002); Nair et al. (2003); Zerroukat et al. (2004). The initial density is the cosine bell,

\[ \rho_0(\lambda, \theta) = \begin{cases} 
1/2 [1 + \cos(\pi r/R)], & r \leq R, \\
0, & r > R, 
\end{cases} \]

(37)

where \( R = 7\pi/64 \),

\[ r = \cos^{-1} [\sin \theta + \cos \theta \cos(\lambda - \lambda_c)] , \]

(38)

and \( \lambda_c = 3\pi/2 \). The bell is advected by a time-invariant velocity field

\[ u = \cos \alpha \cos \theta + \sin \alpha \cos \lambda \sin \theta, \]

(39)

\[ v = -\sin \alpha \sin \lambda, \]

(40)

where \((u, v)\) are the velocity components in \( \lambda \) and \( \theta \) direction, respectively, and \( \alpha \) is the angle between the axis of solid body rotation and the polar axis of the sphere.

Experiments are conducted for \( \alpha = 0 \), \( \alpha = \pi/2 \), and \( \alpha = \pi/2 - 0.05 \). Analytic trajectories are used and \( \Delta t \) is chosen such that 256 time steps correspond to a complete revolution around the globe (the radius of the sphere is set equal to one). Accuracy is measured as relative errors in the \( l_1 \), \( l_2 \), and \( l_\infty \) norms (as defined, for example, in Zerroukat et al. (2004)). Results are reported in Table 2 for a \( 128 \times 64 \) grid (i.e., \( J = 64 \)). It turns out that the relative errors of the newly proposed advection scheme are about the same size as those reported by Zerroukat et al. (2004).

Note that (31) may lead to a non-uniform distribution of particle masses near the polar cap regions for meridional Courant numbers \( C_\theta > 1 \). This can imply a loss of accuracy if a “heavy” extra-polar particle moves into a polar cap region. We verified this for 72, 36 and 18, respectively, time steps per complete revolution (implying a meridional Courant number of \( C_\theta = 1.78 \), \( C_\theta = 3.56 \), and \( C_\theta = 7.12 \), respectively). It was found that the accuracy is improved by applying a smoothing

TABLE 3. Comparison of error norms for solid body rotation with $\alpha = \pi/2$ for different values of the smoothing parameter $\gamma$ in (41) after one complete revolution over a $128 \times 64$ grid (i.e., $J = 64$).

Panel (a): Complete revolution using 72 time step. The meridional Courant number is $C_{\theta} = 1.78$. Panel (b): Complete revolution using 36 time step. The meridional Courant number is $C_{\theta} = 3.56$. Panel (c):

Complete revolution using 18 time step. The meridional Courant number is $C_{\theta} = 7.12$.

operator along lines of constant $\theta$ near the polar caps, e.g.,

$$\rho^{n+1} = \left[1 - \left(\frac{\gamma}{\cos \theta}\right)^6 \frac{\partial^6}{\partial \lambda^6}\right]^{-1} \rho_k^{n+1}, \quad (41)$$

$\gamma \ll \pi/J$, $J = 64$. Here $\rho_k^{n+1}$ denotes the density approximation obtained from (30). The filter (41) is mass conserving and acts similarly to hyper-viscosity. The disadvantage of this simple filter is that $\rho^n \neq \rho$ under zero advection.

Results for $\gamma = 0$ and $\gamma = \pi/192$, respectively, and 72, 36 and 18 time steps, respectively, are reported in Table 3. It is evident that filtering by (41) improves the results significantly. Corresponding results for standard advection schemes can be found in Nair and Machenhauer (2002) for the case of 72 time steps per complete revolution. It turns out that the relative errors of the newly proposed advection scheme with $\gamma = \pi/(3J)$ are slightly smaller than as those reported by Nair and Machenhauer (2002).

(e) Spherical advection: Smooth deformational flow

To further evaluate the accuracy of the advection scheme in spherical geometry, we consider the idealized vortex problem of Doswell (1984). The flow field is deformational and an analytic solution is available (see Nair et al. (1999b); Nair and Machenhauer (2002) for details).

We summarize the mathematical formulation. Let $(\lambda', \theta')$ be a rotated coordinate system with the north pole at $(\pi + 0.025, \pi/2.2)$ with respect to the regular spherical coordinates. We consider rotations of the $(\lambda', \theta')$ coordinate system with an angular velocity $\omega$, i.e.,

$$\frac{d\lambda'}{dt} = \omega, \quad \frac{d\theta'}{dt} = 0, \quad (42)$$

where

$$\omega(\theta') = \frac{3 \sqrt{3} \text{sech}^2(3 \cos \theta') \tanh(3 \cos \theta')}{6 \cos \theta'} \quad (43)$$

An analytic solution to the continuity equation (1) in $(\lambda', \theta')$ coordinates is provided by

$$\rho(\lambda', \theta', t) = 1 - \tanh \left[\frac{3 \cos \theta'}{5} \sin(\lambda' - \omega(\theta') t)\right]. \quad (44)$$
### Table 4: Comparison of error norms at different times \( t \) for spherical polar vortex problem. Computations are performed with a step size of \( \Delta t = 1/20 \) and a 128 × 64 grid.

<table>
<thead>
<tr>
<th>( t )</th>
<th>3</th>
<th>6</th>
</tr>
</thead>
<tbody>
<tr>
<td>( l_1 )</td>
<td>0.0019</td>
<td>0.0055</td>
</tr>
<tr>

</tbody>
</table>

Simulations are performed using a 128 × 64 grid and a step size of \( \Delta t = 0.05 \). The filter (41) is not applied. The exact solution (evaluated over the given grid) and its numerical approximation at times \( t = 3 \) and \( t = 6 \) are displayed in Fig. 4. The relative \( l_1 \), \( l_2 \) and \( l_\infty \) errors (as defined in Zerroukat et al. (2004)) can be found in Table 4. These errors are slightly larger than the ones reported in Nair and Machenhauer (2002); Zerroukat et al. (2004). One can also conclude from Fig. 4 that the numerical solution at \( t = 3 \) is somewhat lagging behind the analytic one while, at \( t = 6 \), the difference between the numerical and analytic solution is very large near the pole.

(f) Rotating shallow-water equations in planar geometry

To demonstrate the behavior of the new advection scheme under a time-dependent and compressible velocity field, we consider the shallow-water equations (SWEs) on an \( f \)-plane (Durran, 1998; Salmon, 1999):

\[
\frac{Du}{Dt} = +fv - g\mu_x, \tag{45}
\]
\[
\frac{Dv}{Dt} = -fu - g\mu_y, \tag{46}
\]
\[
\frac{D\mu}{Dt} = -\mu (u_x + v_y). \tag{47}
\]

Here \( \mu = \mu(x, y, t) \) is the fluid depth, \( g \) is the gravitational constant, and \( f \) is twice the (constant) angular velocity of the reference plane.

Let \( H \) denote the maximum value of \( \mu \) over the whole fluid domain. We also introduce the fluid depth perturbation \( \tilde{\mu} = \mu - H \). The perturbation satisfies the continuity equation

\[
\frac{D\tilde{\mu}}{Dt} = -\tilde{\mu} (u_x + v_y) \tag{48}
\]

which we solve numerically using the newly proposed scheme. The overall time stepping procedure is given by the semi-Lagrangian Störmer-Verlet (SLSV) method with only equation (5.7) from Reich (2006) being replaced by the following steps:

(i) \[
\mu^{n+1/2-\varepsilon} = \mu^n - \frac{\Delta t H}{2} [u_x + v_y]^{n+1/2-\varepsilon}.
\]

(ii) Solve (48) over a full time step using the newly proposed remapped particle-mesh advection scheme with velocities \((u^{n+1/2-\varepsilon}, v^{n+1/2-\varepsilon})\) and initial fluid
The remapped particle-mesh advection scheme

Figure 4. Results of a polar vortex simulation over the sphere. The exact solution and its numerical approximation at time $t = 3$ can be found in panels (a) and (b), respectively. Contours plotted between 0.5 and 1.5 with contour interval 0.05. Panels (c) and (d) display the same results for time $t = 6$.

depth perturbation $\tilde{\mu}^{n+1/2-\varepsilon} = \mu^{n+1/2-\varepsilon} - H$. Denote the resulting fluid depth by $\mu^{n+1/2+\varepsilon} = \tilde{\mu}^{n+1/2+\varepsilon} + H$. We implemented the remapped particle-mesh advection scheme with linear and cubic splines, respectively.

(iii) $\mu^{n+1} = \mu^{n+1/2+\varepsilon} - \frac{\Delta t H}{2} [u_x + v_y]^{n+1/2+\varepsilon}$.

The SLSV method has been implemented using the standard C-grid (Durran, 1998) over a double periodic domain with $L_x = L_y = 3840$ km (see Staniforth et al. (2006) for details). The grid size is $\Delta x = \Delta y = 60$ km. The time step is $\Delta t = 20$ min and the value of $f$ corresponds to an $f$-plane at 45° latitude. The reference height of the fluid is set to $H = 9665$ m. The Rossby radius of deformation is $L_R \approx 3000$ km. Initial conditions are chosen as in Staniforth et al. (2006); Reich (2006) and results are displayed in an identical format for direct comparison.

To assess the new discretization, results are compared to those from a two-time-level semi-implicit semi-Lagrangian (SISL) method with a standard bicubic interpolation approach to semi-Lagrangian advection (see, e.g., McDonald
SLSV \textit{and} SISL \textit{and} SLSV-SISL

Figure 5. Left panels: Computed time evolution, from initial time to \( t = 6 \) days, of PV over the domain \((x, y) \in [0, 3840 \text{ km}] \times [0, 3840 \text{ km}]\) using the semi-Lagrangian Störmer-Verlet (SLSV) method and the remapped particle-mesh advection scheme with cubic splines. The time step is \( \Delta t = 20 \) min. Contours plotted between \( 6.4 \times 10^{-8} \text{ m}^{-1}\text{s}^{-1} \) and \( 2.2 \times 10^{-7} \text{ m}^{-1}\text{s}^{-1} \) with contour interval \( 1.56 \times 10^{-8} \text{ m}^{-1}\text{s}^{-1} \). Middle panels: Time evolution of PV as obtained from a semi-implicit semi-Lagrangian (SISL) method. and Bates (1987); Temperton and Staniforth (1987)). The resulting nonlinear equations are iterated to convergence. It is apparent from Figs. 5 and 6 that the SLSV and SISL simulations yield similar results in terms of potential vorticity advection. Furthermore, the results displayed in Figs. 5 and 6 are nearly identical to those displayed in Fig. 6.1 of Reich (2006). The good behavior of the linear spline implementation of the remapped particle-mesh advection scheme is rather
The remapped particle-mesh advection scheme

surprising and has been confirmed for other simulations such as a shear flow instability.

7. Summary and outlook

A computationally efficient and mass conserving forward trajectory semi-Lagrangian approach has been proposed for the solution of the continuity
equation (1). At every time step a “mass” is assigned to each grid point which is then advected downstream to a (Lagrangian) position. The gridded density at the next time step is obtained by evaluating a bicubic spline representation with the advected masses as weights. The main computational cost is given by the need to invert tridiagonal linear systems in (20). Computationally efficient iterative or direct solvers are available. We also proposed an extension of the advection scheme to spherical geometry. A further generalization to 3D would be straightforward. Numerical experiments show that the new advection scheme achieves accuracy comparable to standard non-conserving and published conserving SL schemes. The main drawbacks of the proposed approach are that higher order splines do not lead to monotonicity preserving schemes and that conservation of mass is not strictly local (in the sense of finite-volume methods).

We note that the proposed advection scheme can be used to advect momenta according to

$$\frac{D}{Dt}(\rho u) = -(\rho u) \nabla \cdot \mathbf{u}. \quad \text{(49)}$$

This possibility is particularly attractive in the context of the newly proposed semi-Lagrangian Størmer-Verlet (SLSV) scheme (Reich, 2006).
